

natural geology of Limburg as design inspiration

The park design is based on the particular geology of the province of South Limburg. Vertical fissures in the earth surface, causing some areas to move up and other areas down, are characteristic for this landscape. This creates **terraces or skegs**. The existing height difference in the park is highlighted by artificial skegs that vary in height. In the interpretation of the areas geology on to the scale of the park the skegs create different spaces for various activities and at the same time prevent the polluted ground from interventions which could destabilize the polluted layer of soil. Several bicycle routes cross the park through the now diverse and playful topography, guaranteeing liveliness on every time of the day.

new terraces dealing with polluted ground structures
